4.3 Pandas and DataFrames ★ Golden

LEARN IT

Pandas is a third-party library for tables. Install once: `pip install pandas` in the terminal (not inside the `.py` file). Convention: `import pandas as pd`.

A **DataFrame** is a 2-D table of rows and columns, like Excel or an SQL table. You can filter, sort and calculate whole columns without writing a `for` loop.

```
import pandas as pd
data = {
    "Name": ["Ali", "Sara", "Ahmed"],
    "Math": [85, 90, 78],
    "Science": [80, 88, 70],
}
df = pd.DataFrame(data)
print(df)
```

OUTPUT

	Name	Math	Science
0	Ali	85	80
1	Sara	90	88
2	Ahmed	78	70

`read_csv('students.csv')` and `read_excel('students.xlsx', sheet_name='Sheet1')` load files. `df.head()` prints the first five rows — use it on large files so you do not flood the screen.

```
df["Total"] = df["Math"] + df["Science"]
df["Average"] = df["Total"] / 2
print(df)
```

OUTPUT

	Name	Math	Science	Total	Average
0	Ali	85	80	165	82.5
1	Sara	90	88	178	89.0
2	Ahmed	78	70	148	74.0

WORKED EXAMPLE

Check: Ali $85+80=165$, $165/2=82.5$. Sara $90+88=178$, 89.0 . Ahmed $78+70=148$, 74.0 .

اردو میں سمجھیں

پینڈا ڈیٹا فریم دیتا ہے۔ ڈکشنری، سی ایس وی یا ایکسل سے لوڈ کریں۔ نئے کالم بغیر لوپ کے پوری قطار پر حساب کر کے بنتے ہیں۔ `head()` صرف پہلی پانچ قطاریں دکھاتا ہے۔

CHECK YOURSELF

1. What is `pd` ?
2. Why not `print(df)` on a million-row file?

Answers: 1. The usual alias for pandas. 2. It would print everything; use `df.head()` .
