4.3 Pandas and DataFrames ★ Golden

LEARN IT

Pandas is a third-party library for tables. Install once: `pip install pandas` in the terminal (not inside the `.py` file). Convention: `import pandas as pd`.

A **DataFrame** is a 2-D table of rows and columns, like Excel or an SQL table. You can filter, sort and calculate whole columns without writing a `for` loop.

```
import pandas as pd
data = {
    "Name": ["Ali", "Sara", "Ahmed"],
    "Math": [85, 90, 78],
    "Science": [80, 88, 70],
}
df = pd.DataFrame(data)
print(df)
```

OUTPUT

	Name	Math	Science
0	Ali	85	80
1	Sara	90	88
2	Ahmed	78	70

`read_csv('students.csv')` and `read_excel('students.xlsx', sheet_name='Sheet1')` load files. `df.head()` prints the first five rows — use it on large files so you do not flood the screen.

```
df["Total"] = df["Math"] + df["Science"]
df["Average"] = df["Total"] / 2
print(df)
```

OUTPUT

	Name	Math	Science	Total	Average
0	Ali	85	80	165	82.5
1	Sara	90	88	178	89.0
2	Ahmed	78	70	148	74.0

WORKED EXAMPLE

Check: Ali $85+80=165$, $165/2=82.5$. Sara $90+88=178$, 89.0 . Ahmed $78+70=148$, 74.0 .

اردو میں سمجھیں

پینڈاز ٹیبل نما ڈیٹا فریم دیتا ہے۔ ڈکشنری، سی ایس وی یا ایکسل سے لوڈ کریں۔ نئے کالم بغیر لوپ کے پوری قطار پر حساب کر کے بنتے ہیں۔ `head()` صرف پہلی پانچ قطاریں دکھاتا ہے۔

CHECK YOURSELF

1. What is `pd`?
2. Why not `print(df)` on a million-row file?

Answers: 1. The usual alias for pandas. 2. It would print everything; use `df.head()`.
